Epigraphs

Learning the Chinese language
requires bodies of iron, lungs of
brass, heads of oak, hands of
spring steel, eyes of eagles, hearts
of apostles, memories of angels,
and lives of Methuselah.

—William Milne, who first
translated the Bible into Classical
Chinese in 1816.

... the Chinese [as] a people [are]
characterised by a marvellous
degree of imbecility, avarice,
conceit and obstinacy...

—James Matheson, cofounder of
Jardine Matheson & Co, 1840s.

China has no philosophy, only
thought.

Jacques Derrida, 2001, Peking
University.

Writing as late as 1898, Huang
Qingcheng 黃慶澄 (1863–1904)
placed the only Chinese
monograph on logic available at
the time in the category of books
on “dialects” (fangyan 方言), that
is, foreign languages, and Liang
Qichao 梁啟超 (1873–1929), who
was considered one of the
foremost authorities in matters of
new knowledge, listed the same
text as a work “impossible to
classify” (無可歸類)—alongside
museum guides and cookbooks.

—The Discovery of Chinese
Logic, Joachim Kurtz

Let us calculate! When controversies arise, there will be no need for dispute between two philosophers. It will suffice to take up their pens, sit down at their slates, and say to each other: Let us calculate!

—Leibniz, *De Arte Combinatoria*, 1666

You savages of the further seas have waxed so bold, it seems, as to defy and insult our mighty Empire. Of a truth it is high time for you to "flay the face and cleanse the heart," and to amend your ways. If you submit humbly to the Celestial dynasty and tender your allegiance, it may give you a chance to purge yourself of your past sins. But if you continue and persist in your path of obstinate delusion, your three islands will be laid waste and your people pounded into mincemeat, so soon as the armies of his Divine Majesty set foot upon your shores.

— Lin Zexu, the Hokkien Qing Imperialist, in Manchu occupied Canton, to HM Queen Victoria's Government, 1839

Definitions

Definition 1 (Siumatgwoon). *A Siumatgwoon, or a Metaphysic, is a set S , paired with the binary relations composition $*$: $S \times S \rightarrow S$ and constitution $|$: $S \times S \rightarrow \{True, False\}$, such that the following axioms hold.*

Axiom 2 (Reflexivity). *For all $a \in S$, $a|a$.*

Axiom 3 (Totality). *For all $a, b \in S$, exactly one of the following holds: $a|b$ or not $a|b$*

Axiom 4 (Transitivity). *For all $a, b, c \in S$, $a|b$ and $b|c$ implies $a|c$.*

Axiom 5 (Composition Constitution). *If $a * b = c$ for some $a, b, c \in S$, then $a|c$ and $b|c$.*

$a * b$ should be read is " a composing with b ", and $a|b$ should be read as " a constitutes b ". You can also read $*$ as "and", "along with", "mixed with", "reacting with", "making love with", etc. You can also read $|$ as "is a part of", "composes", "is a constituent of", "is a component of", "is a sub-object of", etc. Because we are exploring, we will enable maximal leeway in the interpretation of $*$ and $|$, and this we will see, can yield some happy and interesting structures.

Some further clarifications:

- $a \not|b$ iff $a|b = \text{false}$

The above 4 axioms are the core axioms of a Siumatgwoon. There are quite a lot of ways in which you can think about what they are. You can think of them as sure foundations you can rest upon and then launch to explore the space, or you can think of them as a set of definitions that define the metaphysics of an object, in this case a mathematical object. But all mathematical objects are metaphysical objects (though we don't know if all metaphysical objects are mathematical objects - I'd wager not - the first go-to reason one might want to appeal to is Godel's Incompleteness Theorem - I think that's the right direction but Godel won't give us the direct proof to support this intuition - it is likely going to be something beyond mathematical language. Indeed, I think there are metaphysical objects that can be described by natural language, but not mathematical language. But I digress). We can further define other types of Siumatgwoons with further axioms. A taxonomy would then emerge, defined by various properties captured by the additional axioms.

But to capture the logic inside the Sinoglyphs, which is where we are starting - and we are starting there because we believe there's an interesting logic that evolved in there - just like interesting creatures and biosphere usually evolve in isolated and unique environments. To specify certain more restrictive structures, we will now introduce some more axioms, that makes a siumatgwoon simple. They are "simple" because they conform to our mereological intuitions, of both the Sinoglyphs and of the world.

Definition 6 (Simple Siumatgwoon). *A Simple Siumatgwoon S is a siumatgwoon where:*

Axiom 7 (Antisymmetry). *For all $a, b \in S$, if $a|b$ and $b|a$ then $a = b$.*

Axiom 8 (Finite composition). *Every object is finitely composed. For any $x \in S$, $x = y_1 * y_2 * y_3 \cdots y_n$ for some finite number n . In other words, there is no object that is composed of infinitely many objects.*

Axiom 9 (Finite Constitution). *For any $x \in S$, there are only finitely many objects $y_1, y_2, \dots, y_n \in S$ such that $y_1, y_2, \dots, y_n|x$.*

Axiom 10 (Unique Decomposition). *For any $x \in S$, the longest decomposition into objects of S is unique. We can speak of the longest decomposition of an object, because we have axiom 8, which says that every object is finitely composed.*

Axiom 7 antisymmetry says no two distinct objects constitute each other. It rules out circular identity via mutual constitution. So you can't have chains like atoms|humans|universe|atoms - no embedded universes in atoms like in 手塚治虫's 《火の鳥》

Axiom 8 finite composition is a cardinality constraint on the composition operator $*$. Antisymmetry is a constraint on the constitution relation $|$. There's no logical connection between a limit on the number of components in a composition and antisymmetry.

Note that antisymmetry says nothing about how many objects compose another—only about how $|$ relates distinct objects. You could easily construct a model where antisymmetry holds, but some elements are infinitely composed (e.g., think of $x = a_1 * a_2 * a_3 * \dots$ in a naïvely defined algebra).

One should also note that Axiom 7 antisymmetry also rules out the possibility of a simple *siumatgwoon* modeling objects that obey sentences like "man is a part of nature, and nature is a part of man" or "the Tao is part of everything, and everything is part of the Tao" - as clearly the philosophies or metaphysics of those two utterances do not admit that just because $\text{man}|\text{nature}$ and $\text{nature}|\text{man}$, then $\text{man} = \text{nature}$, or that $\text{Tao}|\text{everything}$ and $\text{everything}|\text{Tao}$, then $\text{Tao} = \text{everything}$.

Axiom 9, finite constitution, is a cardinality constraint on the constitution relation $|$. The point of both 8 and 9 is to ground us in the world of finite compositions and finite constitutions.

It says you cannot make a superobject by composing infinitely many objects - composition is finite. Obviously, one can eventually relax this and figure out how things will look. Those sensitive to theological arguments might already detect that finite composition precludes the existence of 吳 in a *Siumatgwoon* so defined. If God is infinite in the sense it has infinitely many attributes, then it is not possible to model God in a simple *siumatgwoon*. However, it seems perfectly intuitive to argue that all things have infinitely many attributes, so nothing can actually be modeled by a simple *siumatgwoon*. Perhaps a fruitful way to then model these objects of infinite attributes, is not to relax the axiom, but to consider a sequence of simple *siumatgwoons* $\mathfrak{A}_0, \mathfrak{A}_1, \mathfrak{A}_2, \mathfrak{A}_3, \dots$, that somehow converge, where the limiting object is indeed an object of infinite attributes. Obviously, to define some kind of limiting mechanism or concept of converge, you'd need to have some concept of open sets, or stronger still, a metric. Let's not get into that.

It will be very interesting to see what kind of objects will be yielded if we relax these two axioms - to infinite compositions and infinite constitutions. How will they look like?

Well, if we relax 9, one can have a *siumatgwoon* S where everything can be infinitely decomposed. So there are no atoms - everything can be cut smaller and smaller and smaller - without end.

This is also a cardinality restriction—this time on the domain of constituents of any object. Antisymmetry only constrains symmetric pairs in $|$, not how many y 's can point to x .

A model could satisfy antisymmetry yet have an object x with infinitely

many distinct constituents y_i such that $y_i|x$, without any pair y_i, y_j satisfying $y_i|y_j \wedge y_j|y_i$.

The uniqueness decomposition axiom, axiom 10, is a uniqueness constraint on the decomposition of an object into its constituents. It says that the longest decomposition of an object is unique. It says that nothing can be made of up of two sets of objects. If you have two different sets of components, then it's not possible to make the same thing. It says: among all decompositions of x , there is a unique one of maximal length (i.e. atomic resolution). This requires some structural property of $*$, perhaps associativity or atomic irreducibility.

Antisymmetry doesn't regulate the structure of compositions—just the equality condition under mutual constitution. Even with antisymmetry, multiple maximal-length decompositions could exist, e.g., due to commutativity or ambiguity in decomposition paths, unless you restrict the structure of $*$.

These are some really weird objects indeed. But they are definitely not anything like the Sinoglyphs - at least not right now.

Does the size of the infinity make things even more interesting? Careful now, we are trying to do what Leibniz didn't do, not to roleplay Cantor.

Before we discuss some further definitions, of Elementals, Generators, Atomics, let us remark some patterns we see in the Sinoglyphs.

The first thing to remark is that Westerners have translated the 邊旁 into "radicals" - as if they're solutions to a quadratic equation, which means then they thought the whole sinoglyph itself is like an equation to be solved.

If we take these radicals, that compose a sinoglyph, we'd say that they are the elementals of the sinoglyph.

The way I came up with the set of definitions for atomics, elementals, generators - was to model the Sinoglyph writing system. Oftentimes, in the Sinoglyph system, as it appears to us, all three sets are the same.

But if we consider a possible extension to the Chinese Character writing system, and simply consider the idealised and fully evolutionarily searched space of possible evolutionary trajectories of the Chinese character writing system, we can arrive at an idealised symbol combination system - that's the Sinoglyph. That Sinoglyph symbol manipulation system, has a structure. And that structure is its Siumatgwoon. And we are now trying to model that structure with some axioms.

Atomics are basically 獨體字. They stand alone. They cannot be decom-

posed, and nothing constitutes them besides themselves.

Elementals are basically any sinoglyph that cannot be fully decomposed. Something else might constitute it, but its constituents can be composed to make the whole the elemental. There's something more in the elemental than just whatever constituting. An elemental might have many many constituents, but the elemental is somehow larger than the composition of its parts. This can be called emergence.

But not all elementals exhibit emergence. Because all atomics are elementals. Since atomics are constituted by themselves, and the atomic needs nothing to be composed with to be itself, atomics are elementals with no emergence.

The elementals largely correspond to the kind of compound sinoglyphs 合體字 that are called phonosemanophores - 形聲字。

Now let's think about how a 形聲字 works. Let's take the classic example of 江河, specifically 河. The Chinese character 河 is a 形聲字.

河

It is composed of 氵 (water) and 可 (ho). Ho is just a name. You might as well right it like this

氵 可

. But the sound is immaterial, it's just an index. It might as well be a, b, c

氵 a , 氵 b , 氵 c

But the important thing is that picks something out. It picks out from the set of all objects that are constituted by water the thing that is "river". You might as very well write it as

氵 *river*

.

The Chinese way of writing "river" is not different from writing it as " 氵 river". It says that "river" belongs to the class of things that are constituted of " 氵"(water); it says "river" is a " 氵 " thing; it says "river" belongs to the set, the class, the category of " 氵 " things; but most importantly, it says: I don't know how "river" is composed, but I do know it is constituted of " 氵 ". So there's something beyond water that makes a river - but I don't know what all the stuff that composes a river is, or *hanc marginis exiguitas non caperet*.

What this immediately suggest is a 系 system. A 金木水火土系 system. A system where elementals can be long to 金系, 木系, 水系, 火系土系 system is a Siumatgwoon, where each 系 contains (but is not limited to) elementals that are constituted of the well, the "Head" of the 系. So the head, of

a 土系 is 土. The head of a 金系 is 金. The head of a 木系 is 木. The head of a 水系 is 水. The head of a 火系 is 火.

We want to capture this - the set of all objects exhibiting emergence from a certain "head". Let us call this set of head x the x -系.

Definition 11 (系 (Hai) Elements). *The set x -系, written as $\langle x \rangle$ is defined to be*

$$\langle x \rangle := \{s \in S : x|s \text{ but } \nexists y_1, y_2, \dots, y_n \in S \text{ such that } s = x * y_1 * y_2 * \dots * y_n\}$$

x -系 elements roughly correspond to the 形聲字 in Chinese characters - if you do not consider the phonetic component of a character to be full elements inside the Siumatgwun but mere indices. In other words, one does not view 江、河、湖、海 as 水工、水可、水胡、水每 but as 水_工 水_可 水_胡 水_每. In this sense, one can see there is no element $y \in S$ such that 水 _{y} = 水_工 = 江.

So what's in an x -系? Say, 木系, the set $\langle 木 \rangle$?

Well, it contains 木, because 木 is cannot be further decomposed. But we also have the other trees, 松, 柏, 柳, 桃, 梅, so we can say

$$木_{公}, 木_{白}, 木_{卯}, 木_{兆}, 木_{每}, 木 \in \langle 木 \rangle$$

But note that 林, 森, 焚 $\notin \langle 木 \rangle$

Does the head of a 系 have to be an atomic element? No, not at all! In fact, the head of a 系 could itself be an elemental like 河, or a proper compound like 雲. Consider the siumatgwun $S = \{雨, 云, 雲, 黔, 黦, 黧, 黻\}$. In this set clearly the atoms are $\{雨, 云\}$, but the elementals are $\{雨, 云, 黔, 黦, 黧, 黻\}$. So $\{黔, 黦, 黧, 黻\}$ are all in $\langle 雨 \rangle$ and in $\langle 云 \rangle$ and also in $\langle 雲 \rangle$.

But there's no reason why elementals, 形聲字, themselves, cannot be the head of a 系. Why shouldn't there be say an object $x = 河_a$ or $river_a$ that we know is a kind of river, but we don't know what all the other constituents are to make it more than just a "typical"river? I mean, it's pretty obvious that The Thames, La Seine, The Hudson, The Jyugong, are all rivers, i.e.:

$$河|Thames, Seine, Hudson, 珠江$$

Which is to say

$$河|河_{Thames}, 河_{Seine}, 河_{Hudson}, 河_{珠江}$$

but we can't write down all the other constituents that make them more than just a river, and not how they differ from each other either. So, i.e.:

$$\text{河}_{Thames}, \text{河}_{Seine}, \text{河}_{Hudson}, \text{河}_{珠江} \in \langle \text{河} \rangle$$

Let us now get some proper definitions.

Definition 12 (Atomics). *An element $a \in S$ is atomic if for all $x \in S$, if $x|a$ implies $x = a$, i.e. a is atomic iff only anything that constitutes a is a itself.*

Definition 13 (Elementals). *An element $e \in S$ is elemental if and only if for all $x_1, x_2, x_3, \dots, x_n \in S$ where $x_1, x_2, x_3, \dots, x_n|e$, we have cannot find a finite sequence drawn from $x_1, x_2, x_3, \dots, x_n$ such that it composes e . In other words, an elemental has no non-trivial decomposition other than $e = e$.*

Note that Siumatgwoons do not swear allegiance to commutativity or associativity. $a * b$ might not equal to $b * a$ and $a * (b * c)$ might not equal to $(a * b) * c$. Both sucrose and fructose have the same molecular formula of $C_6H_{12}O_6$, and so $C, H, O|_{sucrose, fructose}$, but sucrose and fructose are not the same object. Listing the constituents of an object also does not specify how those individual constituents are themselves composed to form components that form the object, which means we don't actually know how many times C, H, O appear in sucrose or fructose. The point of the definition of the elemental, is to say, no matter how you arrange the constituents, no matter how many times each of the constituents appear in a composition, you cannot compose the object from those constituents alone. Again, emergence is at play here.

We quickly define the sets of atomics A and the set of elementals E .

Definition 14 (Atomic Set). *The set $S_A \subseteq S$ is called the atomic set of S . It is the set of all atomic elements inside S .*

Definition 15 (Elemental Set). *The set $S_E \subseteq S$ is called the elemental set of S . It is the set of all elemental elements inside S .*

Lemma 16 (Atomics are Elementals in Simple Siumatgwoons). *All atomics are elementals in simple siumatgwoons. For all simple siumatgwoons S , $A \subseteq E$.*

Proof. Let $a \in A$. a clearly constitutes itself, so $a = a$. If a is not an elemental, then there exists a decomposition $a = b * c$ for some $b, c \in S$. By atomicity, $b = a$ or $c = a$. But then we can apply the same argument again, so $a = a * a$. And we can go ad infinitum, so $a = a * a * \dots$. But this contradicts 8, which states every object in a simple siumatgwoon are composed by a finite number of objects. Therefore, a cannot have any decomposition other than a . Therefore, a is an elemental. \square

Lemma 17 (Atomics). *The decomposition of an atomic in a simple Siumatgwoon is unique. i.e. $a = a$ is the only decomposition of an atomic.*

Proof. As proven above. \square

Definition 18 (Generators). *A set $G \subseteq S$ is a generator of S if and only if every object $x \in S$ can be expressed as a composition (trivial or compound) of objects from G .*

Theorem 19 (Generator sets exist in simple siumatgwoons). *In a simple siumatgwoon, there exists a non-empty subset $G_S \subseteq S$ such that every element $x \in S$ is a product of a finite sequence of elements from G_S , i.e., $x = g_1 * g_2 * \dots * g_n$, where $g_1, \dots, g_n \in G_S$.*

Proof. This is clearly true, because any object $x \in S$ is always a finite composition of itself. So we can just let $G_S = S$. In other words, the set of all objects in S is a generator set of S . \square

Lemma 20 (Elementals are in every generator set). *In a simple siumatgwoon, $E \subseteq G$ for any generator set G .*

Proof. Since any generator set G must generate all objects in S , the generator set G must generate all elementals in E . But elementals have non-trivial decompositions, so they are generated only by themselves. Therefore, to generate the elementals, the generator set G must contain all elementals. Therefore $E \subseteq G$. This also means no generator set can be smaller than E . \square

Lemma 21 (All objects are either elementals or compounds). *For any $x \in S$, x is either an elemental or a compound.*

Proof. If x is an elemental, then it is an elemental. If x is not an elemental, then it has a non-trivial decomposition. Then it is a compound. \square

Lemma 22 (Compounds are composed by elementals). *If an object $x \in S$ is a compound, then it is composed by elementals.*

Proof. If x is a compound that cannot be decomposed into only elementals, then in any decomposition of x you can always find a compound c_1 in the decomposition. Because c_1 is a compound, it can also be decomposed, and in any decomposition of c_1 you must always be able to find a compound c_2 in the decomposition, because if otherwise, c_1 will be composed entirely of elementals, and so will x . But the argument applies for c_2 as well, and you will be able to find a compound c_3 . This can be done indefinitely and you will get a sequence of c_1, c_2, c_3, \dots , and by their nature, we have $\dots, c_1|c_2|c_3|\dots|x$, and they are all distinct. This means, for x , we can find a infinite set of c_1, c_2, c_3, \dots , all constituents of x . But this is in violation of axiom 9, the finiteness of constitution. Therefore, by contradiction, there can be no compound that is composed of only compounds - therefore, all compounds are composed of elementals. \square

Note that in a non-simple siumatgwoon where compositions can go on definitely deep, you can always chop at some level, and whatever higher than the level chopped will yield a simple siumatgwoon - because that seems to be our universe.

Now we move to a stronger theorem.

Theorem 23 (The elementals are a generator set in simple siumatgwoons). *In a simple siumatgwoon, the set of elementals E is a generator set of S .*

Proof. We have proven $E \subseteq G$ for all generator sets G in S . Now we need to prove that for any $x \in S$, $x = e_1 * e_2 * \dots * e_n$ for some $e_1, \dots, e_n \in E$.

From 22, we know that any compound x is composed by elementals. So we can write $x = e_1 * e_2 * \dots * e_n$ for some $e_1, \dots, e_n \in E$.

But since every element in S is either an elemental or a compound, and compounds are all composed by elementals, any element in S is therefore a composition of elementals - in other words, generated by the elementals. Therefore E is a generator set of S . \square

And now we can prove the following theorem.

Theorem 24 (Unique decomposition into elementals). *Let S be a Simple Siumatgwoon, and let E be the set of elementals in S . Then every object in S has a unique decomposition into elementals (up to ordering if composition is commutative; otherwise, strictly unique).*

Proof. By Theorem 23, every object in S can be written as a finite composition of elementals. That is, for any $x \in S$, there exists a decomposition:

$$x = e_1 * e_2 * \dots * e_n$$

with each $e_i \in E$.

Since elementals are by definition indecomposable, no further refinement of this decomposition is possible. Hence, such a decomposition into elementals must be a longest decomposition of x .

But by Axiom 10, every object in a Simple Siumatgwoon has a unique longest decomposition. Therefore, the decomposition of any object into elementals is unique. \square

Now we let us return to x -系 sets, and begin with some simple properties

Lemma 25 (An object is in its own emergence set). *For any $x \in S$, $x \in \langle x \rangle$.*

Proof. By definition, since x , and there is no y_1, y_2, \dots, y_n such that $x = x * y_1 * y_2 * \dots * y_n$. Therefore $x \in \langle x \rangle$. \square

Theorem 26 (Properties of emergence sets). *For any $x, y \in S$, we have:*

- $x \in \langle x \rangle$.
- $x * y \in \langle xy \rangle \subseteq \langle x \rangle, \langle y \rangle \subseteq \langle x \rangle \cup \langle y \rangle$

- if $x \in \langle y \rangle$, then $\langle x \rangle \subseteq \langle y \rangle$
- $x|y$ iff $\langle y \rangle \subseteq \langle x \rangle$
- $\langle x \rangle = \langle y \rangle$ iff $x = y$

Theorem 27 (The emergence set of a set is a subset of the set). *If $\langle x \rangle$ contains compounds if and only if x is a compound.*

Proof. We will prove the converse first, which is the obvious case. If x is a compound, and given $x \in \langle x \rangle$, then $\langle x \rangle$ contains compounds.

Now suppose $c \in \langle x \rangle$ is an compound. And by definition $x|c$. But then since c is a compound, x

□

Then we can prove the following lemma.

Lemma 28 (The emergence of a constituted is emergence of the constituent). *If $a|b$, then $\langle b \rangle \subseteq \langle a \rangle$.*

Proof. If $a|b$, then for any $x \in \langle b \rangle$, because $a|b$ and $b|x$, we have $a|x$. And since x is an elemental, it has no non-trivial decomposition. An object constituted by a and has no non-trivial decomposition is an a -系 object, so $x \in \langle a \rangle$. Therefore, $\langle b \rangle \subseteq \langle a \rangle$ □

Indeed, to illustrate this, consider the following: $\langle \text{水}_\perp \rangle = \langle \text{江} \rangle \subseteq \langle \text{水} \rangle$.

Indeed, $\langle \text{霰} \rangle, \langle \text{隸} \rangle, \langle \text{黠} \rangle, \langle \text{黔} \rangle \subseteq \langle \text{雲} \rangle \subseteq \langle \text{雨} \rangle$

Or to take more interesting example, if we take 江湖 is an object itself of itself, then the set $\langle \text{江湖} \rangle = \{\text{江湖}_1, \text{江湖}_2, \dots\}$ obeys the following

$\langle \text{江湖} \rangle \subseteq \langle \text{江} \rangle, \langle \text{湖} \rangle \subseteq \langle \text{水} \rangle$

Lemma 29 (Every elemental has an atomic constituent). *Every elemental e has an atomic constituent a such that $e|a$. In other words, for any $e \in E$, there exists an $a \in A$ such that $e \in \langle a \rangle$.*

Proof. Assume for contradiction that e has no atomic constituents.

Then we know that there must be an x such that x is a constituent of e , and that $x \neq e$, because if for all x such that $x|e$, $x = e$, then e is atomic.

So let us assume there is an x such that $x|e$ and $x \neq e$. x is either an elemental or a compound. We know all compounds are composed of elementals. So, regardless of whether x is an elemental or a compound, there is going to be an elemental f_1 such that $f_1|x$. Per assumption, this elemental f_1 must not be an

atomic, so another elemental $f_2 \neq f_1$ such that $f_2|f_1$. But the argument can be applied again, indefinitely. But this means, we obtain an infinite set of f_1, f_2, \dots such that $f_i|f_{i+1}$ for all i . But this contradicts 9, which states every object in a simple sumatgwoon are composed by a finite number of objects. Therefore, every elemental has an atomic constituent. \square

Let us now extend definition of emergence and apply it to entire sets.

Definition 30 (X -系). *Let $X \subseteq S$. The X -系 is defined to be*

$$\langle X \rangle := \cup_{x \in X} \langle x \rangle$$

. We call this set $\langle X \rangle$ the emergence set of X , or the set of emergences from X .

Clearly, for any $X \subseteq S$, $\langle X \rangle$ is a unique.

The X -系 set we will be particularly interested in, will be the A -系 set.

Axiom 31 (The emergence set of A). *The A -系 set, $\langle A \rangle$ defined as*

$$\langle A \rangle := \cup_{a \in A} \langle a \rangle$$

is called the emergence set of A , or the set of emergences from A .

There are some interesting properties of an emergence set:

This also implies, the following theorem.

Theorem 32 (Every 系 set is a subset of a 系 set whose head is atomic). *For any $x \in S$, $\langle x \rangle \subseteq \langle a \rangle$ for some $a \in A$.*

Proof. Consider $\langle x \rangle$. x is either an elemental or a compound. And every compound is made of elementals. So there exists an elemental e such that $e|x$. Therefore $\langle x \rangle \subseteq \langle e \rangle$.

By 29, we know that for any $e \in E$, there exists an $a \in A$ such that $a|e$, so we have $\langle e \rangle \subseteq \langle a \rangle$. Therefore, there is an atomic a such that $\langle x \rangle \subseteq \langle a \rangle$

\square

Theorem 33 (Indempotence of emergence). *For any $x \in S$, $\langle \langle x \rangle \rangle = \langle x \rangle$.*

Proof. To aid a sense of intuition, let us swap out x with 雲 for now.

Consider the definition, we have

$$\langle \langle \text{雲} \rangle \rangle := \langle \{ \text{雲}, \text{雲}_1, \text{雲}_2, \dots, \text{雲}_1, \text{雲}_2, \dots \} \rangle = \bigcup_i \langle \text{雲}_i \rangle$$

Here perhaps we assumed that $\langle \text{雲} \rangle$ is countable... (we will one day deal with this.)

Well, note that

$$\langle \langle \text{雲} \rangle \rangle := \langle \{\text{雲}, \text{黔}, \text{黹}, \text{黹}, \text{黹}, \dots, \text{雲}_1, \text{雲}_2, \dots\} \rangle = \langle \text{雲} \rangle \cup \bigcup_{\text{雲}_i \in \langle \text{雲} \rangle - \{\text{雲}\}} \langle \text{雲}_i \rangle$$

And clearly, for every 雲_i , we have $\text{雲} | \text{雲}_i$. Therefore, $\langle \text{雲}_i \rangle \subseteq \langle \text{雲} \rangle$. Therefore, $\bigcup_{\text{雲}_i \in \langle \text{雲} \rangle - \{\text{雲}\}} \langle \text{雲}_i \rangle \subseteq \langle \text{雲} \rangle$.

And so, we have

$$\langle \langle \text{雲} \rangle \rangle = \langle \text{雲} \rangle \cup \bigcup_{\text{雲}_i \in \langle \text{雲} \rangle - \{\text{雲}\}} \langle \text{雲}_i \rangle = \langle \text{雲} \rangle \cup \langle \text{雲} \rangle = \langle \text{雲} \rangle$$

□

Some properties of emergence sets:

Theorem 34 (The emergence set of a set is a subset of the set). *We have*

- $\langle X \cup Y \rangle = \langle X \rangle \cup \langle Y \rangle$
- $\langle X \cap Y \rangle \subseteq \langle X \rangle \cap \langle Y \rangle$

Proof. SHIT

□

Now we can prove something even more interesting.

Theorem 35 (The elementals is identical to A-系 in simple siumatgwoons). *In a simple siumatgwoon, $\langle A \rangle = E$ for any $A \subseteq S$.*

Proof. We will first prove that $\langle A \rangle \subseteq E$, and then we will prove that $E \subseteq \langle A \rangle$.

Let us prove that $\langle A \rangle \subseteq E$.

Well, clearly, for all a where a is an atomic, $a \in E$, because all atomics are elementals. Let us consider any $x \in \langle A \rangle$. By definition, x is such that there is some atomic $a \in A$ such that $a | x$, but there is no way to decompose x into a decomposition containing a . So x is an elemental.

Now let us prove that $E \subseteq \langle A \rangle$.

Recall that for all elementals $e \in E$, there exists an atomic $a \in A$ such that $a | e$, by lemma 29. Therefore, $e \in \langle a \rangle \subseteq \langle A \rangle$. Therefore, $E \subseteq \langle A \rangle$. □

Examples of Siumatgwoons

What are some examples of Siumatgwoons?

The Chinese Characters, 字

The Chinese characters, which inspired this whole mathematical exercise, is clearly a Siumatgwoon. If we exercise the synonym exchange of "Siumatgwoon" with "Metaphysic", then to say the Chinese characters are a siumatgwoon, then this is to say that the Chinese characters is a Metaphysic.

Unfortunately we can't really prove that the Chinese characters are indeed a siumatgwoon, given there's an infinite number of them, and we do not have a generating rule for all Chinese characters.

However, if given any random subset of all Chinese characters, we can prove that it is a siumatgwoon.

Let's consider one example. Let's consider the subset of Chinese characters that are composed of only 1 stroke. Consider the following set of Chinese characters:

$$S = \{\text{日, 月, 皿, 明, 盟, 盥}\}$$

Let us first verify that this is indeed a siumatgwoon. But here's now an interesting question, how are $*$ and $|$ defined? Well, intuitively, we can say a Chinese character $c = a*b$ if c is made of a and b . And we can say that $c|a$ if c appears in the character a . Not terribly helpful or illuminating, perhaps - but is this any less illuminating than defining the valuation of $\phi \wedge \psi$ to be the "0 unless both the valuation of ϕ and the valuation of ψ are 1"? Tautology is where judgement, human intuition, and the exercise of the human choice to grant admission works, and must work - for logic and mathematics to start.

One might note there's something seemingly inherently linked to the behaviour of substrings here. If the logic of a siumatgwoon is merely a logic for substrings, which would be plausible since the project of the siumatgwoon appears to be fundamentally a mereological project, then we might have been rather inflating the intellectual importance of the siumatgwoon. I shall sincerely pray this to not be the case; and I also don't believe this is the case.

So does S satisfy the axioms of a siumatgwoon?

Axiom ?? says any $s \in S$ satisfies $s|s$. This is clearly true. Axiom 3 is

clearly true as well. Since there is no character which is simultaneously constituted by two different sets of characters in S .

Axiom ?? says that for any $s_1, s_2, s_3 \in S$, if $s_1|s_2$ and $s_2|s_3$ then $s_1|s_3$. This is vacuously true, because ha! There are no such three characters in S !

Axiom ?? says that for any $s_1, s_2 \in S$, $s_1 * s_2 \in S$. This is also clearly true - by definition of $*$ and $|$.

So in this very boring example where all 4 axioms are trivially or vacuously true, let us now ask about its atomic set A , its elemental set E .

Now clearly, we have

$$A = E = \{\text{日, 月, 皿}\}$$

So indeed $A \subseteq E$. And indeed in this case, $A = E$, because there are no emergent elements. There are no 系 sets with more than one object - all emergent sets are singletons. This is immediately visible by the fact there are no phonosemanophores 形聲字. And indeed, as proven before, the smallest generator set is indeed E , as every object of S is composed by E .

And the set of compounds $\{\text{明, 盟, 盥}\}$ is clearly disjoint from the set of elementals $\{\text{日, 月, 皿}\}$.

It is also immediately obvious, that S is a simple siumatgwoon, because no character in S is composed of or constituted by infinitely many other characters in E . And clearly, each character is uniquely composed by the elementals, as we can see from the compounds: $\text{盟} = \text{明} * \text{皿} = \text{日} * \text{月} * \text{皿}$.

At this point, it might be really tempting to say if a siumatgwoon is finite, it must be a simple siumatgwoon. But alas, no. We will see this later.

Consider the following siumatgwoon:

$$S = \{\text{骨, 身, 人, 本, 體, 骸, 躰, 体}\}$$

Let us skip the verification of the axioms, and get to the interesting stuff.

Here, we have

$$A = \{\text{骨, 身, 人, 本}\}$$

and

$$E = \{\text{骨, 身, 人, 本, text}\}$$

.

So here, $A \neq E$, because there are emergent elements - phonosemanophores 形聲字.

What we should immediately point out here is that to the seasoned sino-glyph scholar, he will immediately recognize that 體, 骸, 骸, 体 are all variants of the same "character", the same "glyph", the same "sign". They point to the same thing. They are 異體字. It is therefore very tempting to then write that the "true form" of S is actually this:

$$S = \{\text{骨, 身, 人, 本, 體} = \text{骸} = \text{骸} = \text{体}\}$$

Now, if this makes any sense, then we can immediately see that this is not a simple siumatgwoon, because there is a compound with two different decompositions:

$$\text{體} = \text{骸} = \text{骨} * \text{身} \quad (1)$$

$$= \text{骸} = \text{身} * \text{本} \quad (2)$$

$$= \text{体} = \text{人} * \text{本} \quad (3)$$

It is still a siumatgwoon. But it is not a simple siumatgwoon.

One should note that there is something very degenerate in imposing the equality $\text{體} = \text{骸} = \text{骸} = \text{体}$.

On intuitive and philosophical level, it is not appropriate to write that $\text{體} = \text{骸} = \text{骸} = \text{体}$. The most naive argument is probably that the 4 different glyphs are not really saying the same thing. We are not here to do psychology, but one should consider the psychological and performative motivation behind when one writes 骸 instead of 體. One is making the point that the referent of 體 can actually be decomposed into 骨 and 本 - that while one party believes 體 is an emergent object, the other party believes that 體 is actually completely composed by 骨 and 本 ("a body 體 or 骸 is the basis 本 of a bone 骨" - or some other imaginative formulae involving the 骨 and 本). So in this argument, the two assertions carry different ontological commitments on the nature of what a body is. So $\text{體} \neq \text{骸}$.

This is an interesting argument, but the argument allowing for $\text{體} \neq \text{骸}$ is really intuitively compelling. Obviously, when the champion of the variant writes 骸 instead of 體 wherever 體 appears, say in 身骸, 個骸, 本骸, 人骸, 國骸, 聖骸, 靈骸, 天骸, 物骸, he is clearly making the point that the referent of 體 is actually composed by 骨 and 本. In other words, the referent of 體 is the same as the referent of 骸. So $\text{體} = \text{骸}$.

There's also an aesthetic reason why we would be tempted by allowing for $\text{體} = \text{骸} = \text{骸} = \text{体}$, as it seems to allow us this kind of derivation:

$$\text{骨, 本} \mid \text{骸}$$

身, 本 | 躰
 人, 本 | 体
 體 = 體 = 躰 = 体
 \therefore 骨, 人, 本, 身 | 體, 躰, 体, 體

Well the conclusion that "bone", "man", "base", "body", are all constituents of "body" is very intuitively compelling. It's not yet certain what the rules of reference are employed here, but whatever they are, if this derivation is admitted, then we can then work to formalize those rules of reference, and the logical structure of the mathematical object of Siumatgwoon would be richer for it.

But this introduces some very degenerate behaviour into the Siumatgwoon object. The genie responsible is the = relationship. It breaks our semantic definition of * and |, as * and | are no longer matters of considering what the substrings of a Chinese character is, because a character like 體 can now have "hidden" constituents 人, 本, 身.

Also, to allow for = in a siumatgwoon, it might introduce certain undesirable set theoretic behaviour. Not quite sure how to demonstrate this, but the potential for violation is intuitively plausible. Notationally, if we allow for =, in set theoretic language, the objects 體, 躰, 躰, 体 are all just the same object. So notationally,

$$S = \{\text{骨, 身, 人, 本, 體} = \text{躰} = \text{躰} = \text{体}\}$$

is the same as

$$S = \{\text{骨, 身, 人, 本, 體}\}$$

But that's most definitely not what we want to say. And saying that seriously simplifies the structure that one is trying to describe, however naively.

What one is trying to say, is that there is an object S such that

$$S = \{\text{骨, 身, 人, 本, 體, 躰, 躰, 体}\}$$

but the objects 體, 躰, 躰, 体 are "identical", "equivalent", in some sense, up to some kind of relation - are variants of the same thing. Given the use of "identical", "equivalent", and the very symbol =, it seems very compelling that these objects are related by an equivalence relation - reflexivity, symmetry, and transitivity being the core properties governing them. We shall call their relation "synonymy", represented by the symbol \sim . So we can write this instead:

$$S = \{\text{骨, 身, 人, 本, 體, 骸, 軀, 体}\}$$

And so the set theoretic collapse vis-a-vis is avoided.

The synonymy relation will open up significant structures of interest for us to explore, which we will do later.

Now, we must ask the question, are there other siumatgwoons aside from the Chinese characters? Why yes, of course.

The Roman Numerals \mathfrak{R}

One can clearly see that Roman Numerals \mathfrak{R} are a Siumatgwoon, in the same way that anyone can see that the Chinese characters are a Siumatgwoon. However, to appreciate the characteristics that make it a Siumatgwoon, let us consider the subset of Roman Numerals from 1 to 10, which we shall show to also be a Siumatgwoon.

$$\mathfrak{R}_{1,10} = \{I, II, III, IV, V, VI, VII, VIII, IX, X\}$$

We will say that for two elements $a, b \in \mathfrak{R}_{1,10}$, $a|b$ iff the glyph a appears in b . As such, we can say $I|II$ and $I|III$ as an example, and that $V|IV$ and $X|IX$.

For any elements $a, b \in \mathfrak{R}_{1,10}$, if the glyphs ab so written together forms a glyph that also appears in $\mathfrak{R}_{1,10}$, then we'd say that $a * b \in \mathfrak{R}$.

Now, it's clear that Ax 1 is satisfied trivially.

Ax 2 is also satisfied trivially.

Ax 3 is also satisfied.

Ax 4 is also satisfied. As an example: $I|III, III|VIII$ and we have $I|VIII$.

So therefore, $\mathfrak{R}_{1,10}$ is a Siumatgwoon.

It is also interesting to note that as per the definition of $\mathfrak{R}_{1,10}$, it is not compositionally closed. For example, $II * III$ is not in $\mathfrak{R}_{1,10}$. This makes the Siumatgwoon different from a group, where all compositions are contained inside the group. Intuitively, perhaps this suggests the Siumatgwoon is less rich in structure than the mathematical group? Also, note that what $II * III$ should be in $\mathfrak{R}_{1,10}$ is represented by V . Intuitively, we can feel that in some sense, $II * III = V$ - that they're synonymous, identical, referring to the same referent. This is not unlike the presence of variant characters in the Sinoglyphs, such as 體 (body, object) = 骸 = 軀

= 体, or 信 (trust) = 諒 = 仗 = 訖 = 仰...Intuition should hint that this will yield some interesting structures if we pursue the investigation down this path.

This might feel very unsatisfying, because this is no proof. It is merely an observation. One might therefore be tempted to argue, why can't we find a rule or an algorithm or just a function, that maps all the natural numbers to their Roman Numeral representation? Can we then from that algorithm or function, prove that the Roman Numerals are a Siu-matgwoon?

Well let's give it a try. The Roman numeral system is governed by a simple, deterministic algorithm —a greedy function that maps any natural number n to its canonical Roman representation $\tau(n)$. The function operates by iteratively subtracting the largest possible value from n from a fixed, descending list of numeral-value pairs, and appending the corresponding symbol to the output string. For instance, to generate $\tau(1987)$, the algorithm subtracts 1000 (M), then 900 (CM), then 50 (L), followed by three 10s (XXX), 5 (V), and finally two 1s (II), yielding the string `**MCM-LXXXVII**`.

We can define this formally as a function:

$$\tau(n) = s_{i_1} * s_{i_2} * \dots * s_{i_k}$$

such that

$$n = v_{i_1} + v_{i_2} + \dots + v_{i_k}, \quad \text{with each } v_{i_j} \in \{1000, 900, 500, \dots, 1\}$$

and where s_{i_j} is the Roman numeral glyph corresponding to v_{i_j} , chosen at each step to be the largest available $v \leq n$. This ensures that the representation is unique and canonical —a deterministic output of this greedy process.

The same procedure can be extended naturally to represent numbers beyond 3999. Since traditional Roman numerals lack compact notation for such magnitudes, we employ a conventional extension: an overbar denotes multiplication by 1,000. Thus, \overline{V} represents 5000, \overline{X} denotes 10,000, and so forth. In implementation, one may write these as, e.g., ``|V|`` for clarity in ASCII environments. The algorithm remains unchanged: it continues selecting the largest applicable numeral-value pair (now extended with overbarred forms), subtracting, and appending symbols, until the number is fully decomposed.

Under this construction, not only is there a well-defined function $\tau : \mathbb{N}_{>0} \rightarrow \mathfrak{R}$, but we can also use it to define a `**canonical composition operator**`:

$$a * b := \mathfrak{r}(\text{val}(a) + \text{val}(b))$$

and

$$a \mid b \iff \text{multiset}(\mathfrak{r}^{-1}(a)) \subseteq \text{multiset}(\mathfrak{r}^{-1}(b))$$

where $\text{val}(a)$ denotes the numeric value of the Roman numeral a . That is, composition is interpreted as value-addition followed by re-normalization via the greedy function \mathfrak{r} . Constitution $a \mid b$, in turn, can be rigorously defined as multiset inclusion: $a \mid b$ iff every glyph used in the canonical decomposition of a appears (with equal or greater multiplicity) in that of b .

From here, we can prove —rigorously— that the set of all Roman numerals generated via \mathfrak{r} , together with the composition $*$ and constitution \mid , forms a Siumatgwoon. Each of the four axioms holds:

* Reflexivity is immediate: every Roman numeral constitutes itself. * Totality is trivially satisfied since for any pair a, b , either a 's multiset of atoms appears in b 's or it does not. * Transitivity follows from transitivity of multiset inclusion. * Composition Constitution holds because if $c = a * b$, then by construction c is formed from the atoms of both a and b , and hence both are constituents of c .

Ok, that is very impressive. But the problem is that the algorithm doesn't matter. If the algorithm had been modified such that 57 was not written as LVII but instead as LIIIIIII, or XXXXXVII or even XXXXX7 or just 57 or @, the resultant object would still be a Siumatgwoon. Even if each of the numbers were represented by their own unique glyph, the resultant object would still be a Siumatgwoon. The underlying generation rule doesn't matter!

Any Numerals System

The fact that the Roman Numerals are a Siumatgwoon should intuitively suggest that any numeral system is a Siumatgwoon. In fact, let us consider the world's many numeral systems, and see if there is one where it is not a siumatgwoon.

	0	1	2	3	4	5	6	7	8	9
唐字數字	○	一	二	三	四	五	六	七	八	九
唐字數字大寫	零	壹、弍	貳	叁	肆	伍	陸	柒	捌	玖
字喃		𠄎	𠄎	𠄎	𠄎	𠄎	𠄎	𠄎	𠄎	𠄎
蘇州碼子	○	一、一	二、二	三、三	𠄎	𠄎	𠄎	𠄎	𠄎	𠄎
Roman Numerals		I	II	III	IV	V	VI	VII	VIII	IX
Eastern Arabic	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠
Persian	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠
Devanagari	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠
Gujarati	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠
Tibetan	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠

Chinese counting rods		⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠
counting 正		⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠	⊠
Tangut		?	?	?	?	?	?	?	?	?

I don't think there's a single one that's not a siumatgwoon! Most of them are pathological for sure, in the sense that nothing is constituted by anything else, but none of them violate the Siumatgwoon axioms!

The case of the numerals as a Siumatgwoon, or a Metaphysic, is interesting. Numerals all refer to the same referents, the same "things" or "objects", namely, numbers. However, the glyphs in a given numeral system are themselves imbued with a particular set of metaphysical prejudices and judgements. Under the Roman Numeral Metaphysic, the number 3 is composed of 1 and 2, or composed of three 1s. 4 is composed of 1 and 5, but not 3 and 2.

The Polygons \mathcal{P}

Consider the following graph. If we take all the polygons, convex and star, as elements in a set called \mathcal{P} , we can see that it forms a Siumatgwoon. We state this without formal proof for the infinite set \mathcal{P} , but from the subset displayed in the graph below, we can see it is indeed true. A polygon a constitutes polygon b if a appears in b . $\{3\}$, the equilateral triangle, appears in $\{6/2\}$, the star of David, and so $\{3\}|\{6/2\}$

The Schläfli symbol is a recursive description, starting with $\{p\}$ for a p -sided regular polygon that is convex. For example, $\{3\}$ is an equilateral triangle, $\{4\}$ is a square, $\{5\}$ a convex regular pentagon, etc.

Regular star polygons are not convex, and their Schläfli symbols take the form $\{p/q\}$, where p is the number of vertices and q is their turning number. Equivalently, $\{p/q\}$ is created from the vertices of $\{p\}$ by connecting

圖 1: A graph of the polygons

圖 2: A graph of the polygons

every q th vertex. For example, $\{5/2\}$ is a pentagram, while $\{5\}$ is a pentagon.

Note that p and q must be coprime, or the figure will degenerate, in which case we have the following theorem:

$$\{p/q\} = d\{p/d/q/d\}, \text{ where } d = \gcd(p, q).$$

Let us define for any Schläfli symbol $\{p\}|n\{p\}$ for any n . It is intuitively true.

Then clearly axiom 1 is satisfied. Axiom 2 is also satisfied.

Propositional Logic

There are 3 flavors of $*$ in Propositional Logic $P : \wedge, \vee, \rightarrow$.

And we define $\phi|\psi$ if ϕ appears in ψ , for any wff ϕ, ψ .

So $P := \{p, q, r, \dots, \text{and whatever wff formed from } p, q, r, \dots\}$.

Then clearly all 4 of the core siumatgwoon axioms are satisfied.

1. Trivial that all $\phi|\phi$
2. Also trivial that for any ϕ, ψ , either $\phi|\psi$ or $\phi \not|\psi$.
3. Trivial as well that for any $\phi, \psi|\phi * \psi$.
4. Also trivial that if $\phi|\psi$ and $\psi|\theta$ then $\phi|\theta$.

Propositional Logic as a Siumatgwoon has multiple interesting properties:

1. It is compositionally complete.
2. It is also constitutionally complete.
3. Is it a simple siumatgwoon? Are decompositions finite? Yes. Are decompositions unique? Yes, up to reordering. So yes, it's a simple siumatgwoon.

It is arguable whether the \neg operator could be viewed as an object if we view propositional logic as a siumatgwoon.

Furthermore, the propositional logic P has an interesting property - that there are many propositions, by virtue of their internal structure, they

are equivalent in terms of truth value. For example $P \rightarrow P$ and $Q \vee \neg Q$ are equivalent to each other, because no matter the truth value of P or Q , $P \rightarrow P$ and $Q \vee \neg Q$ are always true. So $P \rightarrow P \equiv Q \vee \neg Q$. That's the first thing to note.

The second thing to note is that $P \rightarrow P$ and $Q \vee \neg Q$ are tautologies. They are always true regardless of the truth value of P and Q . One would write that $P \rightarrow P, Q \vee \neg Q \models \top$, where \top is often called "verum". Likewise, $P \wedge \neg P$ is a contradiction, and so is $P \rightarrow \neg P$. One could write that $P \wedge \neg P, P \rightarrow \neg P \models \perp$, where \perp is often called "falsum" or "absurdum".

In most elementary formulations of propositional logic, neither \top nor \perp are not considered wffs or propositions. Therefore if we view P as a siu-matgwoon, \top is not an object. But suppose they are, it could yield some interesting phenomena. Traditionally, then in such propositional logics, one would define negation as such:

$$\neg P \equiv (P \rightarrow \perp), \neg \top \equiv \perp$$

Now let us consider the tautologies and the contradictions. Since all contradictions imply each other, and all tautologies imply each other, but contradictions and tautologies never imply each other, we can comfortably write:

$$P \rightarrow P \sim Q \vee \neg Q \sim \top$$

and

$$P \wedge \neg P \sim P \rightarrow \neg P \sim \perp$$

And given the definition of negation in terms of \top and \perp , we can write that

$$\neg P \sim (P \rightarrow \perp), \neg \top \sim \perp$$

.

Now there are also contingencies, such as PQ . Suppose just like how we've introduced the \top and \perp as objects, let us just write C to signify contingencies, so we can write:

$$P \wedge Q \sim C$$

If you want to think of \top and \perp as truth tables, then \top is a truth table where all the values are true, and \perp is a truth table where all the values are false, and C is any other truth value table.

Now, then let us define a new logic, called propositional logic up to contingency, written as P_i . It has only four atomic objects: \top, \perp, C, \neg , and it has three operators $\wedge, \vee, \rightarrow$ serving as $*$. The definition of a wff is the same as in P .

We know from logic then the following must hold:

$$\begin{aligned}\neg \top &\models \perp \\ \neg \perp &\models \top \\ \neg C &\models C\end{aligned}$$

But also because both $P \rightarrow P$ and $Q \vee \neg Q$ are tautologies, we can also write

The \sim_1 and \sim_2 are not the same, as they highlight the two propositions simulated are similar in different ways.

We can also write that

$$P \wedge \neg P \sim_3 P \rightarrow \neg P \sim_3 \perp$$

Intuitively, we are comfortable replacing \sim_4 with \sim_3 because we know the rules governing their similarity are the same - because the sense governing their similarity, are, intuitively the same. They are always falsehoods.

Now, because $P \rightarrow P \equiv Q \vee \neg Q$ in these sense they are equivalent, we can write

$$P \rightarrow P \sim_1 Q \vee \neg Q$$

So

But are not just equivalent to each other. They are tautologies, tee verum and so far $P \wedge \neg P$ is equivalent to \top .

falsum",[3] "absurdum",[4] or "the absurdity symbol

The Periodic Table of Elements

One can also see that the Periodic Table of Elements is a Siumatgwoon.

In fact, the periodic table of elements, no matter whether the element symbols are written in Roman letters, traditional Chinese characters, or in Japanese Kanji, are all siumatgwoons. The only difference, is that in the latin form, if you take each elemental symbol as indecomposable, i.e you do not admit the "H" and the "e" in "He" as being constituents, then all the elements in the western periodic table are just elementals, and atomics.

But in the Chinese and the Japanese periodic tables, if you take each kanji as decomposable, as in you take into account of the radicals, then the atomics are the elements. The elements might all be elementals, are but not all of them are atomics.

Japanese Kanji coloured periodic table

[illegible]

Consider the old *siumatgwoon* axioms, and a new relation "synonym", represented by \sim , read as "is synonymous with". It satisfies the following axioms.

Synonym Axioms

Axiom 36 (Reflexivity). *S1. (reflexivity) for all $x \in S$, $x \sim x$.*

Axiom 37 (Symmetry). *S2. (symmetry) For all $a, b \in S$, if $a \sim b$ then $b \sim a$.*

Axiom 38 (Transitivity). *S3. (transitivity) for all $a, b, c \in S$, if $a \sim b$, and $b \sim c$, then $a \sim c$.*

Axiom 39 (Compositional Congruence). *S4. (Compositional congruence) If $a \sim a'$, then (if they ax or xa exists):*

- $ax \sim a'x$,
- $xa \sim xa'$

Axiom 40 (Composition Cancellation). *S5. Composition cancellation*

- If $a * b \sim a * c$, then $b \sim c$;
- If $b * a \sim c * a$ then $b \sim c$;

Axiom 41 (Divisor Compatibility). *S6. Divisor compatibility: If $a \sim b$, then for all $x \in S$, $x|a$ iff $x|b$.*

Axiom 42 (Upwards Divisibility). *S7: Upwards divisibility: If $a \sim b$, then for all if $a|x$ then $b|x$.*

A Siumatgwoon is Synonym-Closed if in which if $a * b$ exists and $a \sim a'$ and $b \sim b'$ then $a' * b, a * b', a' * b'$ also exist. Most siumatgwoons, including the Sinoglyphs, are not synonym-closed.

Because of S4, Synonym-Closed Siumatgwoons must have $a * b \sim a' * b \sim a * b' \sim a' * b'$.

S8: Synonym Replacement and Existence Preservation

Synonym replacement completion: if $a * b$ exists, and if $b \sim b'$, then $a * b'$ exists in S as well.

Prior to this, we are rather ambiguous and coy as to whether a and b being synonymous means $b * x$ necessarily exists if $a * x$ exists. I feel we should admit closure for synonym substitutional compositions. We can consider other structure where this axiom is not admitted later.

S9. Multidecomposition if $ab \sim cd$ and $cd = e$ then $ab = e$.

From S4 you'd be able to prove that $a \sim a'$ and $b \sim b'$ then $a * b \sim a' * b'$.

The Quotient Siumatgwoon S/\sim

Starting Point: Synonymy \sim as an Equivalence Relation

Let S be a Siumatgwoon, and let \sim be a synonymy relation on S satisfying:

- \sim is an equivalence relation: reflexive, symmetric, transitive.
- \sim is compatible with composition:
If $a \sim a', b \sim b'$, then $a * b \sim a' * b'$.
- \sim is compatible with divisibility:
If $a \sim b$, then $x|a \iff x|b$ for all $x \in S$.

These give us a solid foundation to define a quotient structure.

The Set S/\sim

Let:

$$S/\sim = \{[a] : a \in S\}$$

where $[a] = \{x \in S \mid x \sim a\}$ is the equivalence class of a .

Defining the Operations on S/\sim

Multiplication

We define:

$$[a] * [b] := [a * b], \text{ if } a * b \text{ exists.}$$

This is well-defined because of compositional congruence (axiom S4).

It is also because that we required if $a * b$ exists, so must $a' * b'$.

That is: if $a \sim a'$, and $b \sim b'$, then:

$$a * b \sim a' * b' \Rightarrow [a * b] = [a' * b']$$

So the result is independent of the representative.

Divisibility

We define:

$$[a]||[b] \iff a|b$$

Again, this is well-defined thanks to the divisibility equivalence axiom (S6):

If $a \sim a', b \sim b'$, given we have the axiom that $a|b \iff a'|b'$ then:

$$[a]||[b] \iff [a']||[b']$$

Thus, $|$ descends to the quotient.

Verifying Siumatgwoon Axioms in S/\sim

Let's verify that the quotient structure inherits the original Siumatgwoon axioms:

- Axiom 1 (Reflexivity of $|$):
Since $a|a \Rightarrow [a]||[a]$
- Axiom 2 (Totality):
For all $[a], [b]$, either $[a]||[b]$ or not.
This follows since $|$ on S has totality, and divisibility is preserved under \sim .
- Axiom 3 (Transitivity):
Suppose $[a]||[b]$ and $[b]||[c]$. Recall the definition that $[a]||[b]$ then $a|b$. It's straightforward.
- Axiom 4 (Composition and divisibility):
We want to prove that if $[a] * [b] = [c]$, then $[a], [b]||[c]$. By definition $[a] * [b] = [c]$ then $a * b \sim c$, and so $a|c$. By the definition of constitutiveness over synonym classes, $[a]||[c]$. The argument same goes for $[b]||[c]$.

Now come axioms 5 and axioms 6. Do they hold in S/\sim , even if they might not hold in S ?

- Axiom 5 (Complete Constructibility and Generators): There exists a non-empty subset $G_S \subseteq S$ such that:

- (Generation) Every element $x \in S$ is a product of a finite sequence of elements from G_S , i.e., $x = g_1 * g_2 * \cdots * g_n$, where $g_1, \dots, g_n \in G_S$

And a Simple Siumatgwoon is one where:

1. E is a generating set, and
 2. that decompositions into elementals are unique.
- Axiom 6. (Finite constitution). For any $x \in S$, there are only finitely many objects $y_1, y_2, \dots, y_n \in S$ such that $y_1, y_2, \dots, y_n | x$.

Let's prove that axiom 5 holds first. And then axiom 6 holds. Then we prove that S / \sim is a simple siumatgwoon.

Consider some element $[x] \in S / \sim$. Given S is a siumatgwoon, we know that any x has a finite decomposition $g_1 * g_2 * g_3 * \cdots * g_n$. Given $x = g_1 * g_2 * g_3 * \cdots * g_n$, we have $[x] = [g_1 * g_2 * g_3 * \cdots * g_n]$, and by the definition of $[*]$ we have $[x] = [g_1 * g_2 * g_3 * \cdots * g_n] = [g_1] * [g_2] * [g_3] * \cdots * [g_n]$. Given this applies to every x in S , it is true of every $[x] \in S / \sim$.

Note that some of the $[g_i]$ might be equal to some other $[g_j]$ if $g_i \sim g_j$.

Now for axiom 6.

Consider $[x] \in S / \sim$. By axiom 6, there only finitely many $y_1, y_2, \dots, y_n | x$. Therefore there are only finitely many $[y_1], [y_2], \dots, [y_n] | [x]$. Note again, that because there could be $y_i \sim y_j$, then the most reduced list of constituents for $[x]$ might be shorter than n .

Axiom 5 (Generators):

If $G \subseteq S$ is a generating set, then $[G] = \{[g] \mid g \in G\} \subseteq S / \sim$ generates all of S / \sim

Hence, S / \sim is a well-defined quotient Siumatgwoon.

Interpretation of S / \sim

- Elements of S / \sim are semantic classes: bundles of expressions that mean the same thing.
- Operations and structure are all inherited from how the parts combine.
- This is essentially a move from syntax to semantics —a form of canonical simplification.

Identity and Atoms in S/\sim

- The set of atomic classes would be:
 $A/\sim = \{[a] \mid a \in A\}$
If synonymy is strong (e.g., if all synonyms of atoms are equal), then this is a true set of atomic meanings.
- The quotient set removes redundancy: if two characters are written differently but function identically, they're collapsed.

A Hierarchy of Synonym Relations

Intuitively speaking, the \sim of 言 \sim 文 that allows us write 信 \sim 儀 seems different from the \sim in 女 \sim 巫, as it does not seem the case that 女 can be exchanged for 巫 in all Chinese characters. This suggests that there is a hierarchy, or rather, a family of synonymous relations, perhaps context dependent.

Some synonyms are more closely clustered together than others. This suggests there is a hierarchy of synonyms.

But to interpret 到 only mean "is synonymous with", leaves us certain phenomena in, or rather, certain ways to "play" Chinese characters, uncaptured.

In Classical Chinese poetry and prose, it is appreciated if couplets are written in a way that characters in the same position belong to "some same class" or objects.

Consider all these lines from 《增廣賢文》:

兩人一般心，無錢堪買金；一人一般心，有錢難買針。馬行無力皆因瘦，人不風流只爲貧。

畫虎畫皮難畫骨，知人知面不知心。錢財如糞土，仁義值千金。流水下灘非有意，白雲出岫本無心。

路遙知馬力，日久見人心。相見易得好，久住難爲人。饒人不是癡漢，癡漢不會饒人。有錢道真語，無錢語不真。長江後浪推前浪，世上新人趕舊人。來如風雨，去似微塵。萬般皆是命，半點不由人。

寧可正而不足，不可邪而有餘。寧可信其有，不可信其無。

To illustrate the point, consider this following sentence, taken from the Analects.

萬方有罪，罪在朕躬。

"Whoever is sinful, the guilt is on my body."

This sentence clearly expresses a monarchist position of politics - one that is shared by both classical Confucianism and medieval Christian political theory. The sovereign, the 君主, is the one who bears the responsibility, and the sins of the 萬方.

Let us simplify and modify this sentence a bit:

君主之國，萬方有罪，罪在君身。

"In a country where monarchs are sovereign, whoever is sinful, the guilt is on the monarch's body."

Now we can apply a naive application of lax synonymy, say on 萬 ("ten thousand") and 兆 ("trillion"), drawing upon they can both be taken to mean "uncountably many" on a metaphoric level, so 萬 ~ 兆, so we get

君主之國，萬方有罪，罪在君身 ~ 君主之國，兆方有罪，罪在君身

We don't have the full algebraic machinery to justify this yet, but it is reasonable.

What I really want to point out, is that in a sense, 君 and 民 belong to the same class - the same class of objects, political objects that is, that can occupy the position of 君. So in a sense, we can write 君 ~? 民. Then, by simply substituting 君 for 民, we get

民主之國，萬方有罪，罪在君身 ~? 民主之國，兆方有罪，罪在民身

Which says, "in a country where the people are sovereign, whoever is sinful, the guilt is on the people's body."

This is not a derivation. Or is it? What kind of derivation is this? What kind of rule of inference are we appealing to? And what is the argument saying? Are we saying if (君主之國，萬方有罪，罪在朕躬) and 君 ~? 民 then we can derive (民主之國，萬方有罪，罪在民身)? What laws govern the behaviour of the ~? Are they the same as the laws governing the behaviour of ~?

The Core Behaviour of Synonym Quotient Siumatgwoons

One core behaviour governing a siumatgwoon with synonymms, and its associated synonym quotient siumatgwoon ($S/\{\sim_i\}$) is that

$$[a] = [b] \iff a \sim_i b \text{ for some } \sim_i$$

In my mind, the way I think about the \iff symbol is that $\phi \iff \psi$ says $\phi \models \psi$ and $\psi \models \phi$.

With this armed in hand, can we now explore the world of how synonyms can be exchanged in composites? Such how atomics may be switched in elementals and compounds, how prefixes and suffixes may be switched in words, how words may be switched in sentences, and how sentences may be switched in paragraphs, and so on.

One promising candidate seems to be this: if $[ab] = [cd]$ and $a \sim x$ then $[ax] = [cd]$.

But this introduces some problems on the \sim relation(s) involved. Let us explicate what $[ab] = [cd]$ says. $[ab] = [cd]$ means $ab \sim_i cd$ for some \sim_i . Suppose $a \sim_j x$, given that we have two, not necessarily identical synonym relations \sim_i and \sim_j , well - what does it mean? Is the new $[ax] = [cd]$ governed by \sim_i or \sim_j ?

Naively, we may just let it pass, and assert and make an axiom out of this:

$$[ab] = [cd]_{(\sim_i)}, a \sim_j x \models [ax] = [cd]_{(\sim_i)}$$

Perhaps this suggests that the sentence, or the higher order \sim , which governs over higher order compounds rather than the lower order ones, takes precedence and dominance. This might be intuitively appealing. After all, it seems reasonable to say that if two words are synonymous then surely you can swap them out in a sentence. But just because two sentences are synonymous doesn't mean the words, or the subjects in the sentence are synonymous. Id est:

$$\sim_j > \sim_i$$

Obviously, this gives us another something for us to potentially axiomatize and structuralise, which means there's another structure here to explore, and axioms for us to configure and calibrate - but let's ignore that for now.

醫醫醫 But doesn't this break in the case 醫醫醫? From variant sinoglyphs, we know:

$$[\text{醫}] = [\text{醫}] = [\text{醫}]$$

And the reason why this chain is admitted as plausible as per the siuatgwoon embedded in the Sinoglyphs is that in Sinitic metaphysics, women 女 and witches 巫 are synonymous, (in a sense, obviously).

Hence, 女 \sim_j 巫. And it is because of this synonymity, that writers, calligraphists, and the extended literati, have evolved to collectively grant legitimacy to this variant exchange symbolized by [醫] = [醫] = [醫].

What we want, is some kind of rule of inference that captures the gist of this proto-rule, this custom, this convention.

Suppose we start with

$$[\text{醫}] = [\text{醫}]$$

which means 醫 \sim_i 醫, but since we also know 女 \sim_j 巫, by the intuition above, we can then say that 醫 \sim_i 醫 \sim_i 巫, and so 醫 \sim_i 醫.

And

and

note that the 医毆醫醫醫 set of variants is a very valuable example and test case for our axioms born out of intuitions. It is one of the few sinoglyphs with two operating semanophores, where one is switched out amongst variants.

Now something trickier - but something we'd probably would very much want - is it possible to produce an axiom such that we can "cancel" out irrelevant components from synonymns so that the "irrelevant" components are eliminated, leaving us only the core synonymous components - that are in a sense responsible for the synonymn of the compound? Now this is very tricky. The sinoglyphs seem to give examples for and against this, sometimes it runs but others it doesn't - probably because the deep underlying aesthetic and associations were not fully graphically expressed.

If we have to reason backwards as to why 女 \sim_j 巫 from 醫 \sim_i 醫, one might say that's because all the other components are the same in both cases, and so the only difference is the 女 and 巫. In the particular case of 醫 \sim_i 醫, they both share 医, the only difference is the 女 and 巫.

In a sense, one can perhaps treat the phonetic component, the name 𠂔 as an object in of itself. If you view it such a way, then you have

$$\text{醫} = \text{医} * \text{女} * \text{𠂔} = (\text{医} * \text{女})_{\text{𠂔}}$$

So, perhaps a promising axiom to capture this is:

If $[x] = [y]$ and the components of x is X and that of y is Y , and if $X - X \cup Y = Y - X \cup Y = \{a_1, a_2, \dots, a_n\}$ then $a_1 \sim_i a_2 \sim_i \dots \sim_i a_n$ for some \sim_i .

Basically whatever they do not share must synonymous.

This proposal is applicable in

體, 骸, 躰, 体

, which yields,

[骸] = [躰] = [体] ⊢ [骨] = [身] = [人]

And in

信, 訖, 諗, 言千, 諱, 忒, 攸, 德

, it gives us :

[信] = [訖] = [諗] ⊢ [人] = [心] = [身]

[信] = [攸] = [德] ⊢ [言] = [文] = [德]

But it is not true that 千~人 nor 辛~人 or 辛~心. So where do the chains end? Well, one slapstick way to explain it away is to say that the 言 in 信, 訖, 諗 and the 言 in 言千, 諱 are not the same - it's just a matter of writing convention that they're assigned the same glyph. "In reality", they are better symbolised as 言₁ and 言₂ respectively.

Another way is to perhaps observe that the poetic interpretation of 信, 訖, 諗 emphasizes that "trust" 信 emerges from "speech" 言 that comen from "man", "heart", or "body", whereas in 言千, 諱, it asserts "trust" 信 (or perhaps "trustworthiness") emerges from "speech" 言 that is "a thousand" 千, or that is "bitter" 辛. Well, the two explanatory structures are not the same... so the factor elimination fails!

This is a naive justification - but perhaps again offers some kind of further structure for us to define and play around with.

It also succeeds in

信訖諗 言千 諱忒攸 德

Which would yeild

法灋沕金
